Trevira 350

The low-pill fibre
Trevira three hundred and fifty
{the low-pill fibre}

Pills—they build up with use and rapidly make a garment look unsightly.

With Trevira Perform the fibres break off before the tiny pills can form.

TREVIRA 350 – THE LOW-PILL FIBRE

Even following periods of intensive wear a garment should maintain a well-groomed appearance. It is in everyday use that balanced qualities show their strengths and that one can make a decisive assessment of the garment. Only in daily performance do the qualities of the fibres reveal themselves, with all their advantages and disadvantages.

When a fabric is subjected to rubbing, bending and twisting, the fibre ends become exposed first. They then form tiny knots: pills.

Whilst with natural fibres their properties are set by nature, it is possible with synthetic materials to control these and produce them to order.

This helps attain the desired goal to develop materials with wear properties that are second to none in terms of wearer comfort and ease of care. In the classic blend, 55% Trevira and 45% wool, the properties of the natural fibre are decisively enhanced by the excellent wear and care characteristics of Trevira fibres.

THE SPECIAL FIBRE FOR LOW-PILL QUALITY

Trevira 350 is a low-pill polyester fibre for the weaving and knitting sectors. The special characteristics of Trevira 350 are embedded in the chemically modified polymer, which has hydrolysable bonds in the polyester chain.

The bonds dissolve during the dyeing process, substantially reducing the transverse strength of the fibre. This reduction in tenacity is intended to lead to any pills that form with wear breaking off. This occurs early in their development.

The great advantage of our Trevira 350 is this: in the raw white state it possesses adequate longitudinal and transverse tenacity to emerge unscathed from the processing stages in spinning, weaving and knitting (provided the information on processing is observed). It only takes on its low-pill properties in the final finished article.

This effect fundamentally distinguishes Trevira 350 from the traditional low-pill polyester from competitors.
FLEX TESTING AND RANDOM TUMBLE PILLING TESTS

The flex test is a measure of the pilling behaviour of individual fibres. The sooner the fibre breaks, the less its tendency to pill! To ascertain the number of flexes, separate fibres are rubbed against a wire until they break. The fibre clamp moves up and down while the wire remains stationary. When a fibre breaks and falls with its own weight, the precise number of flexes completed is recorded in that instant. The process is repeated until all the fibres (approx. 50 in total) have been rubbed through. The arithmetic mean is then calculated from the fifty values obtained.

Flex test carried out on fibres with the FT apparatus

ADVANTAGES OF TREVIRA 350

As a result of the polymer modification, fabrics containing Trevira 350 take on a softer handle. The outstanding low-pill properties make it possible to manufacture yarns and twists that are softer and fabrics that are lighter. In addition to reducing costs, this also produces materials with softer handle. At the finishing stage there is no requirement for additional measures to avoid pilling. Furthermore, Trevira possesses very good dye affinity, in that the same depth of shade can be attained as with traditional low-pill types. However this can be done using some 10% less dye and at dye temperatures that are also 5% lower.

Trevira 350 – Product hallmarks

- Very good low-pill fibre properties
- Pleasant soft feel
- Higher dye yield than with traditional PES types
- Suited to all types of fabric manufacture
- Particularly suited to blends with wool
- Very low absorption of moisture
WORSTED SPINNING

Due to its lower transverse tenacity our Trevira350 is somewhat more sensitive to heavy stress than normal polyester.

◆ CONDITIONS
For processing in blends with wool, the temperature should ideally be at 22°C and relative air humidity at 60 – 65 %.

◆ LUBRICANT
With wool blends it is essential that post-lubrication should take place at the blend drafting stage (approx. 0.2 – 0.3 % active ingredient. Product: e. g. fatty acid ester/antistatic).

◆ RECOMBING
It is normal practice to recomb Trevira 350 in blends, including coarser yarn counts.

◆ RING SPINNING
Depending on spinning geometry, the traveller speed with Trevira/wool blends should be between 29 – 31 m/sec.

◆ WINDING
Speed: 1000 m/min.

◆ TWISTING
Rev/min: 6000 – 7000 (dep. on blend proportions). Use of twist lubricant is recommended. (Active ingredient: 0.6 – 1 %)

COTTON SYSTEM SPINNING

△ CONDITIONS
The Ideal conditions for processing are a temperature of 22°C and 50 % air humidity.

△ CARDING
Actual settings depend on the particular type of machine. However, carding can proceed with the normal settings for polyester. The process should be as gentle as possible (number of revs/min, flat adjustment, delivery speed). Sliver weight should not exceed 5 ktex. Drafting in excess of 80 : 1 should be avoided.

△ RING SPINNING
On no account should the traveller speed exceed 25 m/sec. In processing 100 % Trevira, we recommend dispensing with balloon rings.

△ WINDING
Modern machines can wind at 800 m/min. Older machines may be limited to a max. 600 – 700 m/min.

△ TWISTING
In doubling a spindle revolution of 700 m/min. should not be exceeded. The process requires inclusion of a finish with twist lubricant.
**KNITTING**

1) Optimal yarn twist Alpha 120 – 125 (cotton system) 
   85 (worsted system)

2) Twist-deadened yarn necessary (steam in autoclave at 80° C).

3) For loop formation it is necessary to include adequate finishing with paraffin wax that can be easily washed out.

4) To avoid target rings on cones and to obtain uniform fabric in warp and weft knitting, due attention must be paid to maintaining the same tensile loading on the yarn. Positive thread feed is recommended.

5) To achieve the positive wear properties of Trevira, we recommend an optimal, low-tension finish, e.g. steaming, washing, drying & heat setting at 175 – 190° C.

**WEAVING AND FINISHING**

Spun yarns, in both 100 % Trevira and in blends, can be processed without difficulty in all plants equipped with normal machines. At all stages processing should take place at normal temperatures, i.e. approx. 65 % rel. air humidity and at 21°C ± 2°C room temperature. At the finishing stage, care should be taken, especially when piece dyeing, that a heat setting temperature of 185°C, at 30 seconds contact time, is maintained. In general these processes are adapted to the appropriate end use, where Trevira 350 can be processed on all current machinery.

**CERTAINTY THAT YOU CAN SEE**

This we ensure by means of monitored trademarks. Fabrics bearing the Trevira Perform marque, for instance, are checked not only for dimensional changes after particular stresses, but also for their specific advantages. The latter include resistance to abrasion and tearing, crease resist properties, recovery powers, and of course, resistance to pilling. With Trevira there is reliability in every fibre.

Issue of the Trevira product brand incurs obligations that go beyond the processing stage and extend to the point of sale of the textile material. Minimum proportions of Trevira are prescribed.

Optical, tactile and technological effects may only be designated as Trevira, where all quality criteria are met and proven by means of laboratory tests.
